Jurkat Cells

Jurkat cells are human leukemic T lymphocytes. These cells are particularly responsive to the induction of cell death via apoptosis, rather than the necrosis pathway; also, they are easily maintained in cell culture. The cells are employed in research for further understanding of the apoptosis, programmed cell death, process.

Equipment Used
Beckman Coulter,
Vi-CELL XR
Validated Vi-CELL XR reagent pack

Instrument Settings
When using the Vi-CELL most cells can be analyzed using the default instrument settings. In some instances, certain cell lines may require modification of these analyses parameters. The Vi-CELL intuitive software allows easy user selection of optimum instrument settings thus ensuring accurate results. The instrument settings for the analyses of Jurkat cells are listed below:

- Min. Size (µm) = 6
- Max. Size (µm) = 50
- Number of Images = 50
- Aspirate Cycle = 1
- Mixing Cycle = 3
- Viable Cell Spot Brightness = 75
- Viable Cell Spot Area = 5
- Min. Circularity = 0
- Decluster Degree = Low

Results
The results reported by the Vi-CELL are shown in the Results Section of Figure 1. Percentage viability and total Jurkat cell concentration are 95.6% and 1.05 x 10⁶ cells/ml. The Vi-CELL also reports viable cell concentration, mean cell diameter, size distribution, and average cellular circularity. The cell images may be archived for future re-analyses.

Conclusion
The Beckman Coulter Vi-CELL automates the standard manual method, providing accurate results and removing the subjective nature inherent in the manual method. The significantly greater number of cells tested provides greater statistical confidence in the results than the manual technique.
THE VI-CELL

The VI-CELL automates the widely accepted Trypan Blue Dye Exclusion method. The VI-CELL combines the state of the art in imaging technology, proprietary algorithm and fluidics management.

At the heart of the VI-CELL is the customized liquid handling system. This system, which allows sample aspiration, reagent handling and subsequent instrument cleaning, is fully automated. Once the cellular suspension has been aspirated and mixed with the trypan blue dye, it is pumped to the flow cell for imaging. The VI-CELL can analyze up to 100 images for a given analysis increasing total volume from 15 to 30 times over the manual method with result in a less that 2.5 minutes.

MANUAL TRYpan BLUE DYE EXCLUSION METHOD

As mentioned, the standard method for measuring cell viability is the Trypan Blue Dye Exclusion method. Trypan blue stain (0.4%) is mixed with an equal volume of cells. Viable cells, given their intact membranes, exclude the trypan blue stain; non-viable cells, membrane permeable, stain dark blue. The manual method, however, requires a technician, using a hemacytometer and microscope, to enumerate both stained and unstained cells and manually calculate the percent viability. In addition to being labor intensive, this technique has substantial accuracy error due to its subjective nature.
